Fogging practices of Iowa counties for mosquito abatement

Abstract

Global warming has been associated with an increase of mosquito-borne diseases. Mosquito-borne diseases currently have no prescription remedies. The counties across the state of lowa will increase their fogging procedure, to supplement the increase in mosquitos and mosquito-borne diseases. This study examined which chemicals each county uses for mosquito abatement, the patterns and frequency of spraying, and what patterns of human exposure may be occurring. The county auditor was identified and recruited via email. The county auditors across the state forwarded the email message to the Environmental Health Director, in each county. At county level, they are not in control of the fogging procedure. The individual cities, within those counties, are the ones in control of the fogging procedure. The search engine Google was used to telephone and recruit city administrators across the state of Iowa. These city administrators would also identify, who specifically applies the fogging procedure. These individuals were recruited to partake in the applicator survey. The results showed applicators, across the state of Iowa, are not allowing their pesticide usage be public and research knowledge, rotating their pesticide usage, meeting the FIFRA certifications, and lacking the training for PPE. The state of Iowa should ensure all applicators are FIFRA certified, properly PPE trained, rotate their pesticides, and allow their usage be public and research available.

FOGGING PRACTICES OF IOWA COUNTIES FOR MOSQUITO ABATEMENT

A Graduate Research Paper Submitted to the Division of Health Promotion and Education Department of Curriculum and Instruction In Partial Fulfillment Of the Requirements for the Degree Master of Arts UNIVERSITY OF NORTHERN IOWA

CHAPTER I

INTRODUCTION

The state of Iowa is home to approximately 3 million citizens living within 99 counties. These 99 counties range from rural areas to metropolitan cities. In 2010, 36% of Iowa's population lives within a rural area, while about 64% of Iowa's population lives within an urban metropolitan city. These urban metropolitan cities include Des Moines, Cedar Rapids, Davenport, Sioux City, Iowa City, Waterloo, West Des Moines, Ames, Council Bluffs, Dubuque, and Ankeny. These 11 cities are home to roughly 963,000 residents, or roughly 32% of all Iowans (Brinkhoff, 2015). However, both the urban and rural regions of Iowa share a mutual concern about mosquitos.

Mosquitos are known to be carriers of Encephalitis, Yellow Fever, Dengue Virus, West Nile Virus (WNV), and Chikungunya. As a public health concern, the typical method of controlling the spread of these viruses among various county agencies is to fog. Fogging is the application or treatment of pesticides to exterminate adult mosquitos. Although known to be effective in controlling mosquito populations, it is debated as to whether the pesticides used in common abatement practices are also questionable in their effectiveness. However, it is known that the use of mosquito control pesticides have been associated with increased risks of cancers. Therefore, the counties of Iowa need to explore and find an alternative solution to mosquito control programs, which in the end are ineffective in controlling the mosquito population and the transmission of possible virus to the citizens of Iowa. Thus, the purpose of this cross-sectional study was to describe the chemicals that each county in the state of Iowa use for mosquito abatement and their procedures for triggering a spraying decision, allowing for an estimate of human exposure patterns throughout the state.

In 2015, The State Health Registry of Iowa estimated an incidence rate of 17,000 Iowans to be diagnosed with cancer (University of Iowa, 2015). In 1997, a long-term study of agricultural exposures and chronic cancers among commercial and private pesticide applicators in Iowa and North Carolina. In the first five years, an estimated 59,000 Iowans were enrolled in the study. Iowa also had roughly 32,000 private applicators, 22,000 spouses of private applicators, and 5,000 commercial applicators. The study involved telephone interviews, a mailed dietary questionnaire, and a collection of cheek cell sample from all consenting cohort members. The telephone interviewed about pesticide use since enrollment, current farming and work practices, and health changes. The dietary questionnaire asked about cooking practices and types of foods eaten, since cooking practices and diet can play a role in cancer and other health conditions. Lastly, the cheek cells were used to understand possible links between genetics, exposures, and disease. Currently, the study is in its 23rd year. Since 1997, cohort members have been linked annually or biennially to mortality and cancer registry incidence databases in both Iowa and North Carolina. Among 30,000 spouses of private applicators in the two states reported organophosphates use. An estimated 700 of those spouses were diagnosed with cancer. The study also showed any organophosphates use was associated with an elevated risk of breast cancer. While Malathion, the most commonly used organophosphate, was associated with increased risk of thyroid cancer. The pesticide diazinon was associated with ovarian cancer (Lerro, 2015).

West Nile Virus

West Nile Virus (WNV) was first found in a crow in Scott County, IA in the late summer of 2001. WNV is a mosquito-borne virus that can be transmitted to humans, which can cause encephalitis (inflammation of the brain) or meningitis (inflammation of the lining of the brain and spinal cord) (CDC, 2015). The mosquito genus *Culex pippens* has caused roughly 40,000 known cases and 17,500 deaths within the United States. In 1999, the sentinel case of WNV appeared in New York City. Initially, there were only 62 reported cases of WNV. Shortly thereafter, WNV moved across the United States to California, then reaching Canada and Central America in 2002. In 2012 alone, there were roughly 5,500 cases of WNV in 48 states. It is speculated that the increase in climate temperatures influences the distribution of WNV to the western United States (Soverow, 2009). These increased surface temperatures have also allowed for an earlier transmission cycle between mosquitos through birds and an extended breeding season for mosquitos with more aggressive biting.

Several potential WNV vaccines (ChimeriVax-WN02 and WN-80E) have completed phase I or phase II human clinical trials. These results suggested good safety and immunogenicity. None of the vaccine candidates have progressed to phase III trials (Brandler, 2013). Currently, there are no specific drug treatments or vaccines against the virus. An alternative method to vaccines includes spraying of pesticides. Cities and counties around the Midwest use what is known as "ultra-low-volume spraying", which sprays Pyrocide 7396 from trucks or planes. It is estimated that the average kill rate from using Pyrocide 7396 is roughly 21 to 45 percent. These pesticides have also been shown to kill birds, dragonflies and bats which naturally keep the mosquito population in check. It is also suggested mosquitoes are developing a resistance to commonly used pesticides. These pesticides are typically based on chemicals such as organophosphates, carbamates, pyrethroids, which disrupt natural hormonal systems in humans (Wartman, 2015).

Zika Virus

An additional mosquito virus that's affecting the United States is the zika virus. The zika virus is spread primarily through the bite of an infected Aedes aegypti or Aedes albopictus. In 1947, the zika virus was first discovered in a monkey in Uganda. Before 2015, zika virus outbreaks occurred in tropical Africa, Southeast Asia, and the Pacific Islands. In December 2015, the Commonwealth of Puerto Rico, reported its first confirmed locally transmitted zika case. Currently, local transmission of zika virus has been identified in two areas of Miami-Dade County in Florida. Nationally, there has been a total of 3,358 cases of zika virus. An estimated 3,314 cases were reported as travel-associated. While roughly 43 cases account for locally acquired mosquito-borne cases. As a result, state and territorial health departments are encouraged to report laboratory-confirmed cases to the CDC. The information provided will help the CDC improve their understanding of how and where zika is spreading. The zika virus can also be spread from a pregnant mother to her fetus, sexual intercourse with an infected person, blood transfusions, organ and tissue transplant, fertility treatment, and breastfeeding. An infected person with zika can exhibit either no symptoms or mild symptoms. The mild symptoms an infected person with zika might exhibit are a fever, rash, joint pain, conjunctivitis, muscle pain, or headaches. The symptoms of zika virus are common everyday symptoms, which puts additional people at-risk. A pregnant mother with zika virus can cause their fetus to exhibit a birth defect of the brain called microcephaly. These fetuses and infants infected with zika before birth, also exhibit defects of the eye, hearing deficits, and impaired growth. Additionally, there has been increased reports of Guillian-Barre syndrome in areas affected by zika. Guillian-Barre syndrome is an uncommon sickness of the nervous system, in which, a person's own immune system damages the nerve cells, causing muscle weakness or paralysis (CDC, 2016).

Chikungunya

An additional mosquito virus that affects citizens of Iowa includes chikungunya. Chikungunya is a mosquito-borne viral disease that is transmitted from human to human by the bite of an infected mosquito. This viral disease is characterized by an unexpected fever accompanied by joint pain. The joint pain usually lasts several days to several weeks. In some cases the joint pain persisted for several months, or even years. The mosquito species Aedes *aegypti* and *Aedes albopictus* are most commonly known to transmit chikungunya to humans. Both species are commonly found in the southeastern and southwest part of the United States. Aedes albopictus is also found through the Mid-Atlantic States and the lower Midwest. CDC officials believes chikungunya will behave similar to dengue virus, where imported cases have resulted in sporadic local transmission, but have not caused widespread outbreaks. None of the 200 imported cases of chikungunya between 2006 and 2013 have triggered a local outbreak. However, the added chikungunya-infected travelers coming to the United States increases the likelihood that local chikungunya transmission will occur (CDC, 2014). During January through October, a total of 272 imported cases were reported in Florida, compared to the 1,110 reported in the other 47 contiguous states. Among the imported cases, the most common countries of exposure include Haiti (38%) and the Dominican Republican (30%). In late 2014, Iowa had its first discovered case of chikungunya. A central Iowa male returned from a trip in the Caribbean, where he was bitten by a mosquito carrying chikungunya.

Today, there are no known specific treatments or vaccines for chikungunya. The prevention or reduction of chikungunya virus transmission depends on the control of mosquito vectors or interruption of human-vector contact. Actions should focus on individual protection against mosquito bites, symptomatic treatment of patients, and mosquito proliferation control.

Currently, Iowans generate roughly 3 million waste tires annually (DNR, 2016). Waste tires are seen as ideal breading grounds for mosquitoes. The reasons waste tires are ideal are due to their ability to retain water and their dark colored surfaces to absorb sunlight. In 1991, the state of Iowa provided clear direction on storage and disposal of waste tires to prevent breeding grounds for mosquitoes. The state of Iowa provides best management practices, which include: store as few waste tires as possible, schedule regular pickup of waste tires, keep tire piles covered to prevent entrapment of water, store waste tires in sunny areas, leave waste tires on rims, and do not burn or bury waste tires. The state of Iowa also allows the 99 counties to partake in fogging procedures to control mosquito populations.

Fogging

The use of fog spraying is a form of adulticiding. Adulticiding is the application or treatment of pesticides to exterminate adult mosquitos. The most common form of fogging includes applying pesticides by the use of truck-mounted ultra-low volume spray units driven on public roadways. These ultra-low volume sprays release droplets of synthetic pyrethroid, which stay in the air and kill adult mosquitos on contact. After spraying, pyrethroids settle onto the ground and flat surfaces. The chemical pyrethroid is easily broken down by sunlight, which allows the chemical to last only one or two days within the environment (Illinois Department of Public Health, 2007). Pyrthroids are applied at low levels to control mosquitos, which can aggravate humans with existing respiratory conditions (Walters, 2009). Citizens inhaling higher levels of pyrethroids may experience asthmatic breathing, sneezing, nasal stuffiness, headache, nausea, incoordination, tremors, convulsions, facial flushing and swelling, and burning and itching sensations. The use of pyrethroids has also been linked to hormonal disruption, childhood brain cancers, neurological damage, and thyroid damage. Today, more than 1,000 pyrethroids

have been developed, while only a few are used in the United States. The pyrthroids used in the United States include permethrin, resmethrin, and sumithrin.

Statement of the Problem, its Significance, and the Purpose of the Study

In North America, global warming is lengthening the transmission season of mosquitoborne diseases, such as WNV (Greer, 2008). The virus transmission to humans starts in the spring, with heavy infection in late summer or early autumn (Patz, 2003). It's predicted that the Midwest will experience warmer summers, drier conditions year-round, and milder winter seasons. These climate changes will result in an earlier spring. The earlier spring season would lengthen the transmission of WNV between mosquitos and birds. This lengthened transmission then would result in an increased incidence of human infection. Also, global warming would allow mosquitos to survive in superior numbers as winters become milder. These superior numbers will increase the transmission of WNV from mosquito to mosquito. Ultimately, resulting in an increased incidence rate of WNV (Chuang, & Wimberly, 2012). The counties within Iowa will increase their fogging procedures, to supplement the increase in mosquitos and WNV. The significance of this study is to minimize human health exposure to fogging procedures around the state of Iowa. Fogging procedures contain the chemical pyrethroid. Pyrthroids are applied at low levels to control mosquitos, which can aggravate existing respiratory conditions. Citizens inhaling higher levels of pyrethroids may experience asthmatic breathing, sneezing, nasal stuffiness, headache, nausea, incoordination, tremors, convulsions, facial flushing and swelling, and burning and itching sensations. Pyrethroids have shown to be linked to hormonal disruption, childhood brain cancers, and thyroid damage. Today, more than 1,000 pyrethroids have been developed, while only a few are used in the United States. The purpose of this study, will be to examine, which chemicals each county in the state of Iowa are

using for mosquito abatement and to determine the patterns and frequency of spraying and what patterns of human exposure may be occurring.

CHAPTER II

LITERATURE REVIEW

The state of Iowa is home to approximately 3 million citizens living within 99 counties. A main source of income for Iowa's citizens includes domestic farming. Throughout this chapter, the author will show how agriculture has an indirect effect on mosquito populations, the impacts of WNV, and how pyrethroids affect human health.

Iowa economically relies heavily on agriculture. In 2007, the Census of Agriculture indicates the Midwest region of the United States has a combined market value of crops and livestock products, of an estimated 77 billion dollars (Hatfield, 2012). The use of technological advances in agriculture have provided an increase in crop yield to provide for increased population growth. This economic prosperity comes with an externalized environmental cost, recent agricultural production practices produce significant gas emissions, which in turn, have contributed to global warming. The Environmental Protection Agency (EPA) estimates that 9% of all greenhouse gas emissions are caused by agriculture. Greenhouse gas emissions from agriculture have increased by 17% since 1990. A driving force for this increase has been the 54% increase in combined methane, CH₄ and nitrogen oxides, N₂O emissions from livestock manure management systems (EPA, 2015).

In addition to these agricultural practices, greenhouse gases from human economic and subsistence activities, such as combustion of fossil fuels for electricity, heat, and transportation have contributed significantly to global warming, in the 20th and emerging 21st century. As greenhouse gas emissions from human activities increase, gases such as: nitrous oxide, methane, carbon dioxide, and fluorinated gases build up in the atmosphere. As these gases accumulate in higher concentration in the lower atmosphere, they trap heat. The Earth's surface is heated by

absorbing solar energy, and heat is than radiated back into the atmosphere, where some of the heat is trapped by the greenhouse gases. Global Warming affects temperature, precipitation patterns, and humidity. These factors influence the distribution and spread of vector-borne diseases.

At first glance, it may seem like global warming wouldn't affect the spread of WNV from mosquitos. Rather, the 0.8°C increase in average global temperature over a century and one-half has added about 32°F, to the average yearly temperature of any given year. Based on a range of proxy measurements of temperature, the global average temperate over the last two decades has risen roughly 0.5°C. If the human activities, that generate emissions of greenhouse gases, continue the global average warming may be more than 4°C, by the end of the century (McMichael, 2011). The current total heat flux from Earth to space is an estimated 44.2 terawatts, but the relative contributions from residual primordial heat and radiogenic decay remain uncertain (Lazzaro, 2011). The Catastrophic Man-Made Global Warming Theory proposes that doubling CO₂ directly increases temperatures about 1°C, which then climate pessimists multiply this 3x to 5x more. These increases in warming temperatures cause a widespread distribution of mosquito, vector-borne diseases by increasing the range in which the mosquito can live, increasing the length of the breeding season, and increasing the activity and biting vigor of the mosquitos themselves. (Meyer, 2012).

The increased surface temperature allows for an earlier transmission cycle of WNV, between mosquito and birds. The earlier transmission cycle results in an increased incidence rate of WNV in humans. A recent case-crossover study compared the exposure at the time of WNV onset to an exposure at another time point. The 16,298 WNV cases in the United States suggested: that a 5°C increase in mean maximum weekly temperature was associated with a 32 to 50% increase in WNV incidence (Soverow, 2009). It's predicted that the Midwest, will experience warmer summers, drier conditions year-round, and milder winter seasons. These climate changes will result in an earlier spring. The earlier spring season would lengthen the transmission of WNV, between mosquitos and birds. This lengthened transmission than would result in an increased incidence of human infection (Chuang, & Wimberly, 2012).

WNV was originally isolated in 1937 from the blood of a flushed woman in the WNV province of Uganda. The virus is transmitted to humans through the bite of infected mosquitos, which acquire the virus after feeding on vertebrate hosts, such as birds. The intensity of transmission to humans depends on the numbers and on the feeding behaviors of infected mosquitos. In the United States, the principle genus species responsible for spreading WNV to humans includes Culex pipens, Culex restuans, Culex quinquefasciatus, and Culex tarsalis. In North America, the transmission of WNV increases during the warmer months, with peak activity from July through October (CDC, 2005). Between 1999 and 2004, 16,706 cases of WNV were reported in the United States with the initial illness being reported as early April and lasting to December. The early onset of WNV in April is solely due to the migration of birds to the northern portion of the United States (Hayes, 2006). Temperature also allows mosquitos to increase their viral load while shortening incubation periods. Humidity has also been shown to accelerate blood-feeding and reproduction (Shaman, 2007). A higher weekly cumulative temperature was associated with a 35-83% higher incidence of reported WNV over the next month. The increase in mean weekly dew point temperature was significantly associated with a 9-38% higher incidence of WNV over 3 weeks. Also, 1 day of heavy rainfall within a week was associated with a 29% increase in incidence (Soverow, 2009).

These increases of mosquitos capable of transmitting WNV pose an immediate threat to humans. The treatment of West Nile viral infections are symptomatic, meaning that as symptoms arise they are addressed. If patients with WNV show signs of meningoencephalitis, (cognitive decline, confusion, stiffness and pain in the neck, or loss of consciousness) they should be hospitalized for observation and supportive care. These hospitalizations will also help to rule out Central Nervous System infections or conditions such as: Herpesvirus infection, Guillen-Barre syndrome, and bacterial meningoencephalitis. The most frequent serious symptoms in West Nile encephalitis cases are neuronal dysfunction, respiratory failure, and cerebral edema.

Currently, there is no virus-specific therapy available and no population based, controlled studies examining the use of antiviral agents in humans. Treatments are focused on the management of symptoms wherein corticosteroids, anticonvulsants, or osmotic agents have been utilized. The *prophylactic* use of these drugs to prevent the development of symptoms has not been well studied. The use of these drugs are commonly employed to control the symptoms of WNV. Corticosteroids are chemicals that include steroid hormones, which are produced in the adrenal cortex of vertebrates and are used to reduce inflammation and calm the immune reaction. Numerous antiviral agents though have been studied in WNV-infected cell lines in vitro (testtube). These antiviral agents were also studied in laboratory animals. In limited cases, these antiviral agents were administered experimentally to several patients with advanced West Nile encephalitis. These antiviral agents are classified into three general categories: purine and pyrimidine (ribavirin), interferon α, and human immunoglobulin (Campbell, 2002). Ribavirin is a guanosine equivalent with an in vitro activity against RNA and DNA viruses, including flaviviruses. Further, early evidence suggests that high ribavirin concentrations inhibit the replication and cytopathogenicity of WNV in human neural cells in vitro (Jordan, 2000).

Interferon α has proven, but limited, clinical efficacy on viral infections. Species-specific interferon reportedly protects spinal cord cells from being infected with WNV, while in vitro, when given before exposure to WNV. Interferon has also increased the survival of Vero cells (experimental in-vitro cell line derived from old world monkeys), when applied either before or after WNV inoculation (Anderson, 2002).

In vitro studies, have shown the potential clinical usefulness of these agents in WNV infection. Ribavirin provided limited evidence of a therapeutic effect in WNV-infected mice. The effectiveness of these and other agents against this virus *in vivo* (controlled human trials) has yet to be determined. There have also been no clinical trials in West Nile meningoencephalitis patients. Globally, only a small number of patients have ever received antiviral drugs for West Nile meningoencephalitis. In a retrospective Israeli study of 233 West Nile meningoencephalitis patients, including 37 who empirically received ribavirin, multi analysis showed that ribavirin had no effect on WNV mortality (Chowers, 2001).

There have been several potential WNV vaccine studies (ChimeriVax-WN02 and WN-80E), which have completed phase I or phase II human clinical trials. Neither ChimeriVax-WN02 nor WN-80E have been able to complete phase III of human clinical trials due to poor results in phase I and II. As a result of work to-date and because active research is continuing, there is no drug specific treatment protocol (outside of supportive care to address symptoms) or vaccine available for WNV. Prevention of infection, therefore; remains the best solution for counties across the United States. Public health departments seek to prevent the incidence of WNV and the increasing population of mosquitos, ideally this would be through the use of Integrated Pest Management, IPM programs. Given that the only really viable solution to the control of WNV is IPM; it is imperative that the IPM program minimize excessive use of pesticides so that one environmental health problem, WNV, does not lead to another- excessive pesticide exposure.

In an ideal world, the mosquito control within the United States has evolved from reliance on insecticide applications for control of adult mosquitos (adulticide) to integrated pest management programs. These integrated pest management programs include surveillance, source reduction, larvicide, biological control, as well as public relations and education. The use of surveillance programs allows for tracking diseases harbored by wild bird and chicken flocks; vector-borne pathogens in mosquitos; and evaluation of adult and larval mosquito cycles and larval habitats. When established mosquito larval and adult thresholds are exceeded, control activities are initiated. Source reduction approaches strive for the elimination of larval habitats and encouragement of habitats unsuitable for larval development, thus, eventually decreasing adult population numbers. The use of public education is critical in considering source reduction as individual homeowners must participate in efforts to reduce standing water and harborage areas. There are counties across the United States, which have public school education programs to teach their children what they and their families can do to prevent mosquito proliferation.

The use of biological controls involves the use of predators that eat larvae and pupae. The commonly used biological controls include the mosquito fish, *Gambusia affinis* and *Gambusia holbrooki*. Mosquito fish have a drawback since they also feed upon other organisms such as tadpoles, zooplankton, aquatic insects, and other fish eggs (Courtenay, 1989). However, mosquito fish are the most common supplemental biological control agent for mosquito control. The main reason for mosquito fish being the most common biological control is they're easily raised. Another alternative to insecticides includes the use of mosquito traps. Mosquito traps use attractants such as compressed carbon dioxide, burning propane and octanol to attract mosquitos,

and fans to control airflow along with containers designed to entrap the mosquitos. Carbon dioxide exhalation on the part of animals is easily detected by mosquitos and is how they are able to zone in on their "prey". However, the use of mosquito traps is expensive costing well over \$1,000 each.

The use of mosquito fish and traps are not widely used in the state of Iowa. The state of Iowa allows the use of pesticides. Pesticides, used by state and local agencies to control mosquitos, must contain warning labels to minimize risks to human health and the environment. These pesticides are sprayed by public health employees or professional pesticide applicators, who are specifically trained to follow proper safety precautions and directions for their use. Pesticide applicators who mix, load, and apply the concentrated pesticides must use personal protective equipment (PPE). The use of PPE helps minimize exposure from the fogging device and while pumping pesticides into the spray equipment. Adulticides require small droplets of the pesticide to drift through areas where mosquitos are flying. The larger droplets of adulticide, which land on the ground can cause undesirable effects on non-targeted organisms. These organisms that are affected by the toxicity of the pesticide include birds, fish, wildlife, aquatic invertebrates, and honeybees. These pesticides are applied in a concentrated form such as 29.6 mL per acre. Typically, ground-level, ultra-low volume applicators produce droplets 8 to 30 microns in size, with none greater than 50 microns. Further, large droplets in excess of 50 to 100 microns can damage automobile paint finishes, due to the solvent carriers used to disperse the pesticides. The pesticides responsible for these damages to automobile paint finishes include Malathion, Naled, and Fenthion. The pesticides used for mosquito control in ultra-low-volume are Malathion (Fyfanon, Atrapa, Prentox), Naled (Dibrom, Trumpet), fenthion (Batex),

permethrin (Permanone, AquaResilin, Biomist, Mosquito-Beater), resmethrin (Scourge), sumithrin (Anvil), and pyrethrins (Pyrenone, Pyronyl) (Rose, 2001).

Unfortunately, the undesired effects of permethrin, resmethrin, and sumithrin are a direct impact on human and wildlife health. When permethrin is applied to plants, it can last on the leaves between 1 and 3 weeks. Scientists applied permethrin to soil and then planted sugar beets, wheat, lettuce, and cotton. The scientists found trace amounts of permethrin residue in the edible parts of the plant, even 30 to 120 days after planting. Trace amounts have also been found in bananas, collard greens, squash, and watermelon. When permethrin is eaten it can cause sore throat, abdominal pain, nausea, and vomiting (NPIC, 2009). Permethrin was originally classified by the International Agency for Research on Cancer (IARC) as "not classifiable as to its carcinogenicity to humans" in 1991. The U.S. EPA later decided that permethrin was "likely to be carcinogenic to humans" if it was eaten. This decision was based upon the chemical structure of permethrin, how it is biotransformed and distributed in the body, and laboratory tests that indicated neoplasia (tumor development) in mice. The chemical structure of permethrin contains piperonyl butoxide a known carcinogen. The use of permethrin is also extremely toxic to fish and other animals that live in either salt or fresh water. The EPA has established regulations that prohibit the direct application to open water within 100 feet of lakes, streams, rivers, or bays (NPIC, 2009).

Resmethrin exhibits a half-life 30 days and is primarily broken down by sunlight. Scientists applied resmethrin to surfaces exposed to sunlight and observed a half-life of 20 to 90 minutes. The scientists then applied resmethrin to tomato and lettuce plants, where 55 to 82% of resmethrins chemical structure was broken down within 2 hours. Despite resmethrin being easily broken down within the environment, it possesses a severe threat to human health. Direct contact with resmethrin can cause burning, itching, tingling, and numbness. The effects of absorbing it through the skin or breathing it include abnormal sensations of the face, dizziness, fatigue, and irritability to sound and touch. In the most severe cases, resmethrin has been associated with liver and thyroid problems, interfering with the immune and endocrine systems. The chemical resmethrin was classified by the U.S. EPA as "likely to be carcinogenic to humans." This classification was based on tests that showed increased liver tumors among female and male rats, which were fed resmethrin for 2 years. The chemical structure of resmethrin contains pipernyl butoxide, which the EPA classifies as a known carcinogen. Resmethrin has been found to be extremely toxic to honeybees, fish, and invertebrates, such as pink shrimp and water fleas (Stahl, 2002).

A scientist at the Mount Sinai School of Medicine discovered that sumithrin should be considered a hormonal disruptor (Go, 1999). Sumithrin has been shown to affect the endocrine systems in both humans and wildlife. The scientist's study indicated that pyrethroids disrupt the endocrine system by mimicking the effects of female hormone estrogen. This can result in breast cancer in women and a lowered sperm count among men. When estrogen levels were elevated, old cells were not removed from the body and cell proliferation occurred, either benign or malignant. The National Institute for Occupational Safety and Health Registry of Toxic Effects of Chemical Substances lists sumithrin as a kidney toxicant and suspected neurotoxicant. The product Anvil contains 10% sumthrin and 10% piperonyl butoxide, these two chemicals together ensure that Anvil is considered a carcinogen. Sumithrin is highly toxic to bees and fish. The label on Anvil, states "This product is toxic to fish. For terrestrial use, do not apply directly to water, or to areas where surface water is present or to intertidal areas below the mean high water mark." (CDC, 2015)

The effects of low-volume droplet dispersal of mosquito pesticides pose damages to automobiles and severe health risks to humans. There are several measures that an individual can undergo to protect themselves from mosquito spraying. These protective measures include staying indoors, close windows and doors, turn off air conditioners, wash exposed skin surfaces with soap, cover outdoor tables and play equipment or rinse them with soap and water after fogging, bring laundry, pet dishes, and toys inside, cover vegetable gardens, and cover ornamental fishponds (Citizens Campaign for the Environment, 2015). Re-entry intervals are set to protect people against poisoning by pesticides, if they enter a treated area too soon after application without PPE. The label on the pesticide container provides information on re-entry intervals (Canadian Centre for Occupational Health & Safety, 2016). These re-entry intervals can range from 10 minutes to several hours depending on the product.

FIFRA

The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) is the Federal statute that governs the registration, distribution, sale, and use of pesticides in the United States. Before a pesticide may be sold or distributed in the United States, it must be registered with the EPA. The worker protection standards (40 CFR Part 170) requires that facilities that handle pesticides adopt workplace practices designed to reduce or eliminate exposure to pesticides and must establish procedures for responding to exposure-related emergencies. FIFRA prohibits registration of pesticides that generally pose unreasonable risks to people, including agricultural workers, or the environment. If EPA believes the risks to workers posed by a pesticide are excessive, it can take actions such as requiring additional label warnings or requiring labeling that mandates use of protective clothing. The FIFRA certification is required for restricted pesticide use not for general category and applicators not applying to own land. The FIFRA certification is exempted for farmers and hired hands (EPA, 2015).

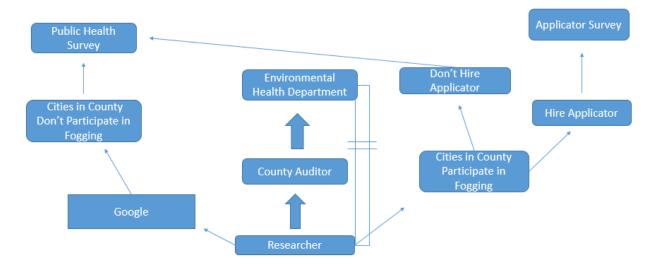

CHAPTER III

METHODOLOGY

The purpose of this cross-sectional study was to describe the chemicals that each county in the state of Iowa use for mosquito abatement and their procedures for triggering a spraying decision, allowing for an estimate of human exposure patterns throughout the state. The goals of the research was to identify what triggers an applicator to spray, are applicators properly FIFRA certified, are precautions consistently used to protect the public post spraying, and are pesticide chemicals properly rotated to prevent pesticide resistance in the target pest population?

Research Design

A cross-sectional research design will be used with a survey instrument employing both quantitative and qualitative questions. Spraying practices in the 99 counties of Iowa will be described. This is a questionnaire evaluation study. This questionnaire evaluation study involves the analysis of data collected from a population, at one specific point in time. The research will examine the amount of the chemicals used in the fogging practices and how often these chemicals are sprayed, as well as the criteria used to trigger fogging events. This data will be useful in determining which chemical or chemicals are most likely being released into the environment and available for human contact. This research design didn't need approval from the Institutional Review Board (IRB) since asking the counties and applicators questions about their jobs.

Systems Diagram Research Process

Initially, the researcher restricted the search to each public health department and/or city administrator. The researcher then used study procedure occurred between January 2016 and October 2016. The procedures used to conduct the research included survey questionnaires, online survey instruments, interview schedules, e-mail, telephone, and the use of an automobile for direct site visits. There referrals from these individuals to focus the study on only the individuals responsible for fogging in each of Iowa's 99 counties. The timing of the were two survey questionnaires. The first survey questionnaire will be used to examine which counties use fogging, to measure the frequency of their fogging, and how they decide to trigger a fogging event. The second questionnaire will be used to examine the applicators mode of treatment, the effectiveness of the fogging treatment, and if the pesticide can affect other organisms. The interview schedules were assigned to each county based on their schedules for ease of participation. The use of a telephone allowed the researcher to survey the applicator without having to drive directly to each county, if acceptable to the participant. The use of an automobile will be used in case the individual wants a face to face interview and cannot use an on-line survey format. The consistent use of a single questionnaire and consistency in interview procedures and techniques will aid with reliability and validity, although it is acknowledged that in-person interviews or telephone interviews may yield more complete data than on-line questionnaires. The use of Iowa's Economic Development website will be used to classify each county as either rural or urban.

There were several methods used to recruit participants. Initially, each county auditor was sent an email requesting which cities in his or her county fog for mosquitoes. The county auditors that e-mailed back typically forwarded my email message to the environmental health department in their county. The environmental health department knew if the county was in charge of fogging or the individual cities. The environmental health department mentioned the individual cities, in which, they knew sprayed in their county. The telephone was then used to contact the city administer in these cities, to confirm that their city participated in a fogging procedure. An additional question was asked to the city administer to determine if the city sprays themselves or hire an applicator. After, the city participated in the questionnaire; the applicator was contacted to participate as well. The counties, where the environmental health department, did not know if cities sprayed within their county. The search engine Google was used to obtain a list of cities within that county. The list consisted of cities ranging from a population of around 100 people to several thousand. The search engine Google provided each cities city hall and city administers number. Then used a telephone to contact these individuals' cities to see if participated in a fogging procedure. If no city within that county used a fogging procedure, a representative of that county was still asked to participate on behave of that county. When a city within that county used a fogging procedure, I would ask them to participate in my survey. If the city refused, the remaining

cities with that county were. If that was the only city within the county that spray, the survey questions were answered with refused to answer.

The researcher will use the program JMP Statistical Discovery from SAS to analyze the information provided from the foggers of all 99 counties, in Iowa. The JMP Statistical links graphics, statistics, and data all together. JMP encourages the researcher to ask more questions, which improves chances of making breakthrough discoveries. JMP also allows the researcher to examine their data without having to rerun an analysis as new questions arise.

CHAPTER IV

RESULTS

Descriptive Univariate Analyses

Results presented in Table 1, show the number of Iowa's rural and urban counties, as identified by Iowa Department of Economic Development. These results were collected from responses to the questionnaire. The full applicator univariate analyses data can be found in the Appendices A on pgs. 62-77.

Table 1

Demographics: Iowa Counties and Location

	Rural	Urban	Total
Iowa	35	13	N=48

Table 2

Demographics: Job Title and Location

	Rural	Urban	Total
Demographics	36 (73.5%)	13(26.5%)	*N = 49
Job Title			
Wastewater Superintendent	1	0	1 (2.0%)
Street Superintendent	7	1	8 (16.3%)
Public Works Employee	0	1	1 (2.0%)
Public Works Director	3	2	5 (10.2%)
Parks Maintenance Specialist	0	1	1 (2.0%)
Parks & Rec Supervisor	0	1	1 (2.0%)
Operator in Charge	1	0	1 (2.0%)
Director of Health	1	0	1 (2.0%)
No Response	22	7	29 (59.2%)
No Job Title	1	0	1 (2.0%)

* One County gave two responses

As shown in Table 2, there were 35 (73.5%) rural counties and 13 (26.5%) urban counties in the sample. Most rural and urban applicators gave no response to, "*disclose the job title of the individual who oversees the fogging procedure*" (59.2%). The street superintendent is commonly the individual in charge of the fogging procedure in rural and urban counties (16.3%).

Demographics: Certified Federal Insecticide Rodenticide Pesticide Handler and Location

	Rural	Urban	Total			
Demographics	(n =13)	(n =6)	*N=19			
Certified Federal Insecticide Rodenticide Pesticide Handler						
Yes	4	1	5 (26.3%)			
No	7	5	12 (63.2%)			
Other	2	0	2 (11.1%)			

* 29 Participants did not answer the question

As show in Table 3, most pesticide applicators are not certified Federal Insecticide Rodenticide Pesticide handlers (63.2%).

	Rural	Urban	Total
Demographics	(n =35)	(n =13)	N=48
PPE Trained			
Yes	13	5	18 (37.5%)
No	0	1	1 (2.1%)
No Response	22	7	29 (60.4%)

Demographics: PPE training and Location

As shown in Table 4, most applicators had no response to the question, "*are treatment handlers supervised and trained in the use of PPE*" (60.4%). While 37.5% of applicators responded that their treatment handlers are supervised and trained in PPE.

Demographics: Pesticide Brand Name and Location

	Rural	Urban	Total
Demographics	(n = 36)	(n = 13)	*N = 49
Pesticide Brand Name			
Univar Environmental Sciences	1	1	2 (4.1%)
Permethrin	1	0	1 (2.0%)
Mosquito Mist One ULV	3	0	3 (6.1%)
Masterline Kontrol 4-4	2	1	3 (6.1%)
Kontrol 30-30 Concentrate	1	0	1 (2.0%)
Evoluer ULV 4	1	0	1 (2.0%)
Envion RTU	0	1	1 (2.0%)
Evolver 30/30	1	0	1 (2.0%)
Clarke-Biomist 4+4	4	1	5 (10.2%)
Clarke-Duet	0	1	1 (2.0%)
Anvil 2+2	1	2	3 (6.1%)
5% Skeeter Abate	1	0	1 (2.0%)
No Response	20	5	25 (51.0%)
Unsure	0	1	1 (2.0%)

*One County gave two responses

As shown in Table 5, the majority of rural and urban applicators had no response to, *"what pesticide they use in their fogging procedure"* (51.0%). Clarke-Biomist 4+4 is the most commonly used pesticide among applicators, who responded to the survey (10.2%).

Demographics: Effectiveness and Location

	Rural	Urban	Total
	(n =13)	(n =6)	*N =19
Effectiveness of Pesticide			
Not Effective	1	0	1 (5.2%)
Between Not Effective and Moderately	1	0	1 (5.2%)
Moderately Effective	3	1	4 (21.1%)
Between Moderately Effective and Extremely	4	4	8 (42.1%)
Extremely Effective	4	1	5 (26.3%)

*29 Participants did not answer question

As shown in Table 6, most applicators rate the effectiveness of their pesticide as, "*between moderately effective and extremely effective*," (42.1%) and "*extremely effective*" (26.3%).

Demographics: New Products and Location

	Rural	Urban	Total
	(n =13)	(n =6)	*N =19
Choose New Pesticide			
Yes	5	2	7 (36.8%)
No	8	4	12 (63.2%)

*29 Participants did not answer question

As shown in Table 7, most applicators wouldn't choose another pesticide if it were available and effective (63.2%). There were several applicators that would change their product for another pesticide, if it was available and effective (36.8%).

Table 8

Demographics: Application Indicators and Location

	Rural	Urban	Total
	(n =43) (n =17) *N =60
Application Indicators			
Public Input	7	1	8 (13.3%)
Land Study	1	0	1 (1.6%)
Standing Water	1	1	2 (3.3%)
Weather	5	2	7 (11.6%)
Mosquito Population	6	4	10 (16.6%)
Cost	1	0	1 (1.6%)
Entire Town	0	2	2 (3.3%)
No Response	22	7	29 (48.3%)

*10 Counties gave two responses

*1 Counties gave three responses

As shown in Table 8, most applicators had no response to, "*what indicators are used when deciding to fog*," (48.3%). "*Mosquito Population*" (16.6%) and "*Public Input*" (13.3%) were the two biggest indicators among applicators on when to fog.

Results presented in Table 9, shows the number of the urban and rural individual cities within Iowa's 99 counties, as mentioned by Iowa Economic Development. These results were collected from the **<u>Public Health survey</u>**. The full results of the Public Health Univariate Data can be found in the Appendices C on pgs. 109-130.

Table 9

Demographics: Iowa Counties and Location

Rural	Urban	Total
79	23	*N=102

* 3 Counties had 2 Individual Cities Participate

Table 10

Demographics: In Charge and Location

	Rural	Urban	Total
	(n =77)	(n =22)	*N=99
Department in Charge of Applying Pesticide			
Yes	15	8	23 (23.2%)
No	47	12	59 (59.5%)
Other	15	2	17 (17.1%)

* 3 Participants did not answer the question

* 3 Counties have 2 responses

As shown in Table 10, the majority of cities within Iowa's 99 counties are "*not in charge of applying their* pesticide" (59.5%). While the cities within Iowa's 99 counties are "*in charge of applying*" their pesticide accounts for 23.2%.

Table 11

Demographics: Mosquito Resistance to Pesticide Monitored

	Rural	Urban	Total
	(n =71)	(n =18)	*N=89
Mosquito Resistance to Pesticide Monitored?			
Yes	7	5	12 (13.5%)
No	64	13	77 (86.5%)

* 13 Participants did not answer the question

* 1 County gave both answers

As shown in Table 11, the majority of the state of Iowa's 99 counties don't monitor mosquito resistance to their pesticide (86.5%).

Bivariate Analyses

The Bivariate Analyses used to depict statistically significant data was ANOVA, Pearson's Chi-Square, and Likelihood ratios. These Bivariate Analyses showed no statistical significance, when examining the FIFRA certified by all questions, as well as, county by all questions. Since there was so statistical significance in these findings, the use of rural and urban to all questions was used. The use of rural and urban was used to help identify statistical trends within the data. The full Applicator Bivariate Analyses can be found in Appendices B pgs. 78-98.

Table 12

Applicator Data

	Rural	Urban
Brand Name used in Fogging	No Response (57.1%)	No Response (38.5%)
Procedure	Mosquito Mist One (8.6%)	Anvil 2+2 (15.4%)
	Clarke-Biomist 4+4 (8.6%)	
Ground or Aerial Treatment	Ground (92.3%)	Ground (100%)
or Both	Both Treatments (7.7%)	
New Pesticides Available and	Yes (38.5%)	Yes (33.3%)
Effective, Change Product	No (61.5%)	No (66.7%)
Are the Pesticides you use in	Broad Spectrum (23.1%)	Broad Spectrum (16.7%)
Broad Spectrum, or for	Specific Organisms (76.9%)	Specific Organisms (83.3%)
Specific Organisms		
Are the Pesticides you use in	Yes (7.7%)	Yes (16.7%)
rotation with other Pesticides	No (92.3%)	No (83.3%)
FIFRA Certified	Yes (30.8%)	Yes (16.7%)
	No (53.8%)	No (83.3%)

36

PPE Training	No Response (62.9%)	No Response (53.8%)
	Yes (37.1%)	Yes (38.5%)
Records kept regarding the	All 3 Records Kept (61.5%)	All 3 Records Kept (80%)
use of the pesticide?	Not all 3 Records Kept	Not all 3 Records Kept (20%)
(Application Rates, Sites, and	(38.5%)	
Amount)		
Pesticide affect other	Yes (38.5%)	Yes (50.0%)
Organisms	No (53.8%)	No (33.3%)
Indicators used when	No Response (62.9%)	No Response (53.8%)
deciding when and where to	Public Input (8.6%)	Mosquito Population (15.4%)
apply treatment		
Chosen Sites contain water	Yes (46.2%)	Yes (66.7%)
sources	No (46.2%)	No (33.3%)

As shown in Table 12, a majority of both rural (76.9%) and urban (83.3%) applicators are using their pesticide for specific organisms. These rural (92.3%) and urban (83.3%) applicators are not rotating their specific organism pesticides. A majority of rural (61.5%) and urban applicators (80.0%) are keeping records regarding the use of their pesticide (application rates, sites, and amount). The Bivariate Analyses showed statistical significance, when examining several public health questions by rural and urban. The use of Pearson's Chi-Square was used to determine statistical significance.

Table 13

Correlation Analyses by County Fogging: All Subjects (N=102)

Correlation analysis item	df	Chi-Square	p-value
Urban Counties by County Fogging	1	5.414	0.0200

Urban Counties are more statistically likely to fog more than rural counties (p=0.0200).

*See Appendices D pg.131

Table 14

Correlation Analyses by Outside Hire: Rural and Urban (N=40)

Correlation analysis item	df	Chi-Square	p-value
Rural Counties by Outside Hire	9	19.196	0.0236

Rural Counties are more statistically likely to use Mosquito Control of Iowa than urban counties (p=0.0236).

*See Appendices D pg. 136

Table 15

Correlation Analyses by Mosquito Resistance Monitored: Rural and Urban (N=89)

Correlation analysis item	df	Chi-Square	p-value
Urban Counties by Monitored	1	3.952	0.0468

Urban Counties are more statistically likely to monitor mosquito resistance than rural counties

(p=0.0468).

*See Appendices D pg.139

The Bivariate Analyses used to depict statistically significant data was ANOVA,

Pearson's Chi-Square, and Likelihood ratios. These Bivariate Analyses showed no statistical significance, when examining rural and urban counties by being in charge of applying their pesticide, public notification, and what the recommended time period was for the public to stay inside. The full Public Health Bivariate Analyses can be found in Appendices D pgs. 131-146.

Table 16

Public Health Data

	Rural	Urban
In Charge of Applying	Yes (19.5%)	Yes (36.4%)
Pesticide	No (61%)	No (54.5%)
New Pesticides Available and	Yes (7.90%)	Yes (9.10%)
Effective, Change Product	No (51.3%)	No (68.2%)
FIFRA Certified	Yes (17.1%)	Yes (19.0%)
	No (64.5%)	No (76.2%)
Public Notification	Not Notified (7.8%)	Website and Newspaper
	Website, Newspaper, News	(18.2%)
	Announcement (5.20%)	Website and News
		Announcement (13.6%)
Time Recommended for	None (8.0%)	None (4.8%)
Public to Stay Inside	Late Evenings (5.3%)	Evenings (4.8%)
Public Told to do During	None (11.8%)	Stay Inside (18.2%)
Fogging	Stay Inside (7.90%)	None (9.1%)

As shown in Table 16, the majority of both rural (51.3%) and urban (68.2%) Public Health officials "*wouldn't change their pesticide*" for a newer effective pesticide. 18.2% of urban public health officials "communicate with the public what to do during fogging" 18.2%. While 7.90% of rural Public Health officials "communicate with the public what to do during fogging".

CHAPTER V

CONCLUSIONS

In North America, global warming is lengthening the transmission season of mosquitoborne diseases, such as WNV (Greer, 2008). The virus transmission to humans starts in the spring, with heavy infection in late summer or early autumn (Patz, 2003). The communities across Iowa use pesticides to control the mosquito population and to reduce the likelihood of transmission of mosquito-borne disease to humans. The goals of the research were to identify what triggers an applicator to spray, are applicators properly FIFRA certified, are precautions consistently used to protect the public post spraying, and are pesticide chemicals properly rotated to prevent pesticide resistance in the target pest population? The two questionnaires revealed negative findings on what is occurring across the state of Iowa, in regards to mosquito abatement. There were 19 applicator responses out of 48 applicators to the applicator questionnaire. The applicators, who provided no response, should legally be required to respond. The community has the right to know what chemicals the applicator is spraying in the air. It's critical for the public to know what these chemicals are to ensure safety for themselves and their children, before spraying hours for precautionary measures. Besides the public, researchers should have the right to gather what chemical the applicator is using, to determine its implications on the public's health. The applicators across the state of Iowa are doing a great job of maintaining records pertaining to their pesticide (application rates, sites, and amounts). Since the applicators are maintaining this information, the information should be easily obtainable to researchers and the public.

Another alarming, data finding was a majority of pesticides used across the state of Iowa are not being rotated. The overuse of a specific organism's pesticide, without rotation, can cause mosquitoes to become resistant overtime. Ultimately, the pesticide would become ineffective while exposing the public to toxic chemicals. The Public Health insisted that a majority of counties are not monitoring mosquito resistance. The applicator questionnaire revealed an alarming finding about FIFRA certification and PPE training. The majority of applicators across the state of Iowa, are not FIFRA certified, as well as, providing proper PPE for fogging practices. These findings could also be a result of the applicator not properly understanding the questions. The FIFRA certification is required for restricted pesticide use not for general category and applicators not applying to own land. The FIFRA certification is exempted for farmers and hired hands. The Public Health questionnaire revealed that public input is an important factor, on deciding when to fog for mosquitoes. The two main triggers for applicators applying their pesticide are mosquito population and public input. These triggers are concerning for several reasons. The toxic pesticides are being released into the air, while mosquito's carrying no diseases, could be present. Ultimately, we are killing non-disease carrying mosquitoes and other harming the bee population. The bee population is critical for the human race survival, because the honeybee pollinates roughly one of every three bites of food. The mosquito applicators are providing positives for the state of Iowa. The pesticides the applicators are using were rated between moderately effective and extremely effective. The use of pesticides has not caused anyone to relocate across the state.

Recommendations

The questionnaire's data revealed a concerning picture, in regards to, mosquito abatement across the state of Iowa. The state of Iowa could partake in several recommended measures.

Initially, the state should ensure all mosquito applicators are FIFRA certified. The state of Iowa could ensure all mosquito applicators are FIFRA certified by having the applicator send in yearly reports. The applicators do a great job of maintaining records pertaining to their pesticide (application rate, sites, and amounts). There should be a change to the federal and/or state law to make baseline data, knowledge available to all people. This change in law would ensure the safety for the citizens. There also should be an increased measure in mosquito monitoring, because of the applicators not rotating their pesticide usage. The rotation of pesticide usage would help prevent mosquitoes from becoming resistant overtime. This rotation would also ensure that the citizens of Iowa are not exposed to the toxic pesticide, when the pesticide becomes ineffective in mosquito abatement. There also should be extension training for Public Health workers on IPM. The extension training would allow Public Health workers to incorporate IPM to reduce mosquito populations.

APPENDICES

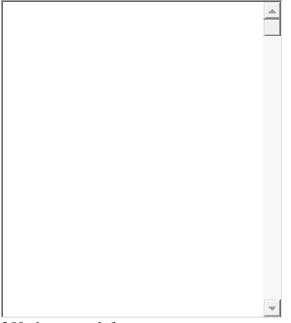

Applicator Questionnaire

Applicator Fogging Survey *Required Question(s)

*****1. What county do you identify with in Iowa?

*2. What is the brand name of the insecticide you utilize in your fogging procedure?

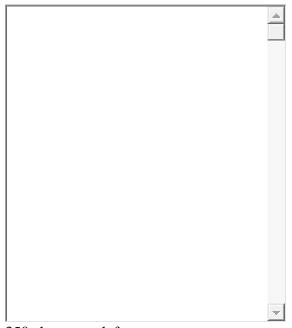

350 characters left.

*3. On a scale, rate the effectiveness of your insecticide/fogging treatment based on your seasonal results.

Not Effective		Moderately Effective		Extremely Effective
0	\odot	0	0	0

500 characters left.

*4. What is the application rate of the treatment you use in gallons per acre?

350 characters left.

- *****5. Do you use ground or aerial treatment?
 - Ground only
 - Aerial only
 - O Both Ground and Aerial Treatment
 - Comment:

		-

★6. If other pesticides were available and effective, would you choose another product? If yes please provide a product preference in the comment box.

O Yes

٠

O No

1		

500 characters left.

- *7. Are the pesticides you utilize used in a broad spectrum, or for specific individual organisms?
 - O Broad Spectrum
 - Specific Organisms
 - Other
 - Comment:

	-
	-

*****8. Is the pesticide used in rotation with other pesticides that have a different mode of action?

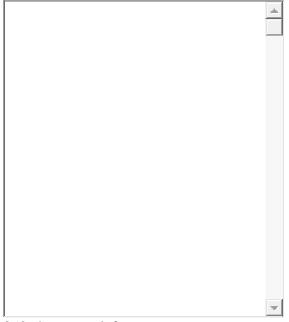

O Yes

•

- O No
- Other
 - Comment:

*****9. What is the job title of the individual who oversees the fogging procedure?

350 characters left.

10. Do you have an individual(s) that is a Federal Insecticide Fungicide Rodenticide Act certified pesticide handler? If so, what is their job title?

 No Other Comment: 	0	Yes	
	0	No	
	0	Other	
		• Comment:	
			-
•			
•			
•			
•			
•			
•			
		•	-

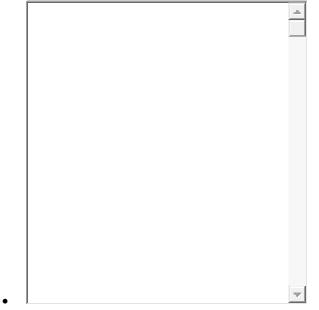

*11. Are treatment handlers supervised and trained in the use of personal protective equipment (PPE)? Are PPE provided? Is PPE training provided? If PPE training is provided, how often is training and who performs the training?

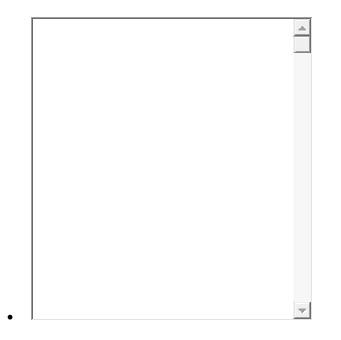

- 12. Are records kept regarding the use of this pesticide? (i.e. application rates, sites, dates, methods, personnel, budget) Please check all that those records include.
 - □ Application Rates
 - □ Sites
 - Dates
 - Methods
 - Personnel
 - □ Budget
 - □ Amount
 - □ None

• Comment:

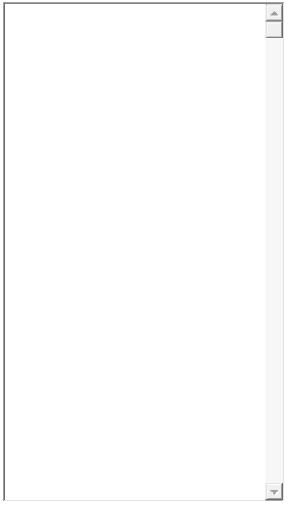

500 characters left.

- *13. Can your pesticide affect other organisms (i.e. insects, mammals, fish life) If yes, what types of organisms?
 - Yes
 - O No
 - O not Know
 - Comment:

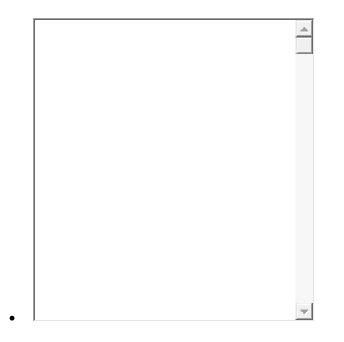

*14. What are the indicators that are used on deciding when and where to apply treatment?

*****15. Do these chosen sites contain water sources?

- Yes
- O No
- Other
 - Comment:

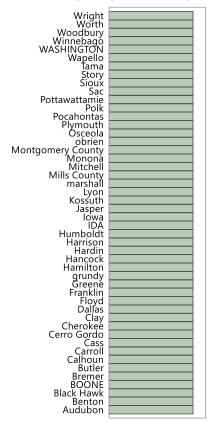

*16. What period of time (i.e. days, hours, minutes) is recommended to the public when advised to stay indoors/ avoid fogging operations?

Appendices A

Public Health Questionnaire

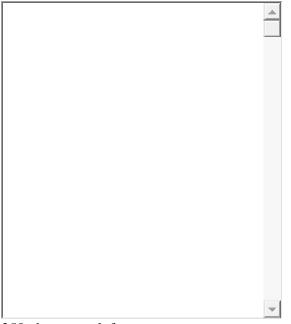

*****Required Question(s)

*1. What county do you identify with in Iowa?

350 characters left.

*2. What is the brand name of the insecticide you utilize in your fogging procedure?

350 characters left.

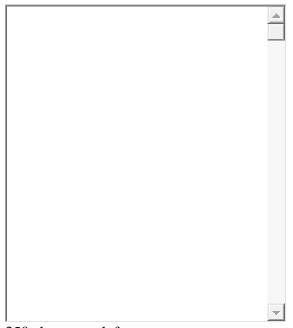

*****3. On a scale, rate the effectiveness of your insecticide/fogging treatment based on your seasonal results.

Not Effective		Moderately Effective		Extremely Effective
0	\odot	0	0	0

-

500 characters left.

*4. What is the application rate of the treatment you use in gallons per acre?

350 characters left.

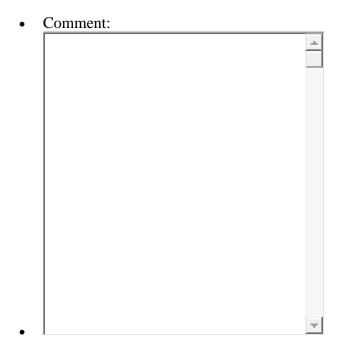

- *****5. Do you use ground or aerial treatment?
 - Ground only
 - Aerial only
 - Both Ground and Aerial Treatment
 - Comment:

		-
		$\overline{\mathbf{v}}$

- ★6. If other pesticides were available and effective, would you choose another product? If yes please provide a product preference in the comment box.
 - Yes

•

O No

500 characters left.

- *7. Are the pesticides you utilize used in a broad spectrum, or for specific individual organisms?
 - O Broad Spectrum
 - Specific Organisms
 - Other
 - Comment:

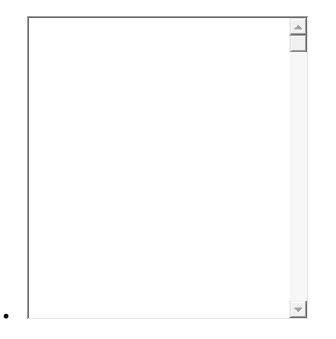

<u>.</u>
-

*8. Is the pesticide used in rotation with other pesticides that have a different mode of action?

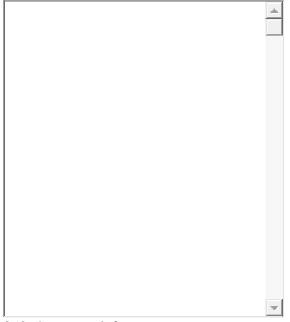

O Yes

•

- O No
- Other
 - Comment:

*9. What is the job title of the individual who oversees the fogging procedure?

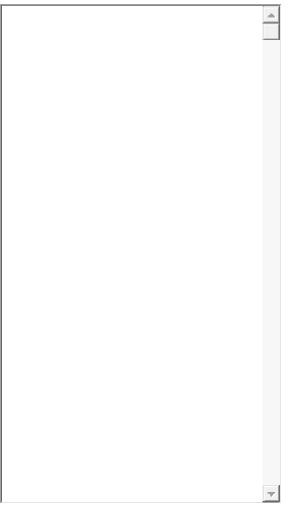

350 characters left.

10. Do you have an individual(s) that is a Federal Insecticide Fungicide Rodenticide Act certified pesticide handler? If so, what is their job title?

0	Yes	
0	No	
0	Other	
	• Comment:	_
		<u> </u>
	•	-

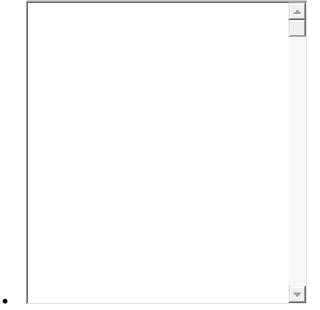

*11. Are treatment handlers supervised and trained in the use of personal protective equipment (PPE)? Are PPE provided? Is PPE training provided? If PPE training is provided, how often is training and who performs the training?

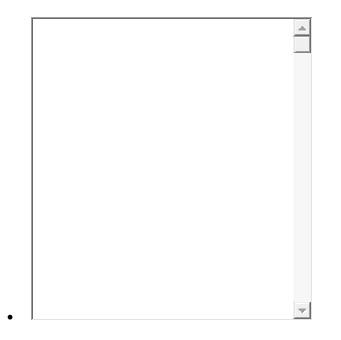

- 12. Are records kept regarding the use of this pesticide? (i.e. application rates, sites, dates, methods, personnel, budget) Please check all that those records include.
 - □ Application Rates
 - □ Sites
 - Dates
 - Methods
 - Personnel
 - □ Budget
 - □ Amount
 - □ None

• Comment:

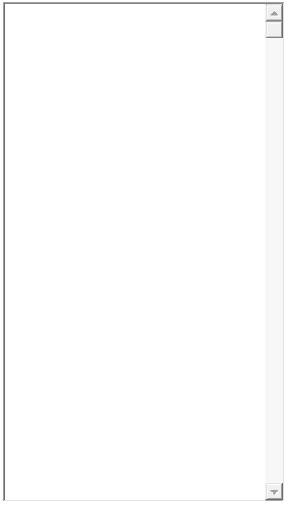

500 characters left.

- 13. Can your pesticide affect other organisms (i.e. insects, mammals, fish life) If yes, what types of organisms?
 - O Yes
 - O No
 - O not Know
 - Comment:

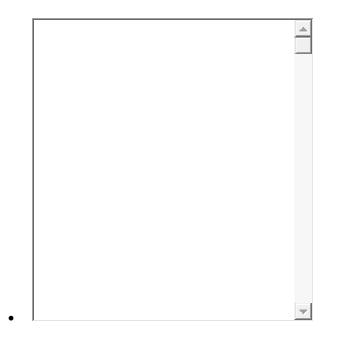

*14. What are the indicators that are used on deciding when and where to apply treatment?

*****15. Do these chosen sites contain water sources?

- O Yes
- O No
- Other
 - Comment:

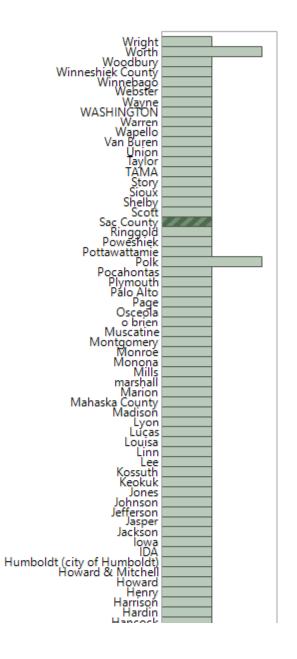

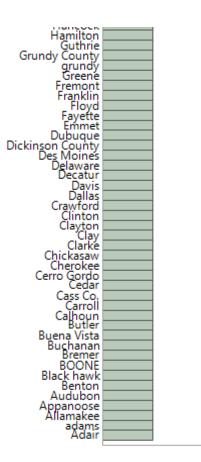

*16. What period of time (i.e. days, hours, minutes) is recommended to the public when advised to stay indoors/ avoid fogging operations?

at least once a week under heavy mosquito pressure and sometimes twice a week
Yes but didn't respond back
When Called
Weekly during Mosquito Season
We only fog as conditions require. The timing may be once to twice a week if warranted. We do not do any preventative spraying.
We contract with a company and they perform 16 fogging treatments from the middle of May to mid-September.
We apply multiple times during the summer season
WE contract with mosquito control of Iowa. WE budget for 12 sprayings a year. depending on mosquito populations we may use more or less than that number
The City is treated at least four to five times a year. They will include additional treatments at no extra cost as needed during wet years.
