Figure 1: On the night of April 21 and the morning of April 22, it may be possible to see meteors of the Lyrid meteor shower. The meteors will appear to originate or radiate from above the constellation Lyra. Figure 1 shows the approximate location of this radiant. Unfortunately, the Moon, which rises at 12:11 a.m., is in a waning gibbous phase and is 75 percent illuminated. Once the Moon rises it will be difficult, if not impossible, to see all but the brightest meteors. On a clear dark night, approximately 15 meteors per hour may be seen.
Figure 2: Approximately 30 minutes before sunrise on April 26, the Moon, Saturn, Mars and perhaps Mercury may be visible. The Moon will be illuminated 36 percent. Saturn will be located about 7° to the right of the Moon. Mars will be directly east approximately 11° above the horizon. Seventeen degrees to the lower left of Mars, very near the horizon, is the planet Mercury. Binoculars may be necessary and would certainly improve your chances of seeing these planets in the morning twilight. The Sun will rise at 6:17 a.m.

Figure 3: On the night of May 3 and the morning of May 4, it may be possible to see meteors of the Eta Aquarid meteor shower. The meteors will appear to originate or radiate low on the eastern horizon, from above the constellation Aquarius, at 2:00 a.m. Figure 3 shows the approximate location of this radiant. Fortunately, the Moon is new and will not interfere with meteor observing. On a clear dark night, about 20 of these meteors per hour may be seen.

Figure 4: Early in the morning on May 10, Saturn and Mars will be visible. Saturn can be found in the constellation Capricornus, about 23° above the horizon. Mars is in the constellation Pisces and can be found about 45° to the lower right of Saturn. Mars will be close to the horizon, so binoculars may be necessary to see it. Sunrise is at 5:59 a.m.
**Figure 5:** On the night of May 10, the Moon and *Jupiter* are high in the southwest in the constellation Leo. The Moon is illuminated 67 percent. Jupiter is approximately 9° to the upper right of the Moon.

**Figure 6:** The Moon, *Saturn*, and *Mars* will be visible low in the southeast before sunrise on May 25. The Moon is illuminated 43 percent. Saturn is 25° to the right of the Moon. Mars is only about 5° above the horizon, approximately 33° to the left of the Moon. Binoculars may be necessary in order to view this planet. Sunrise is at 5:46 a.m.

**Figure 7:** On the night of June 5, the Moon is illuminated 30 percent. *Jupiter* is located in the constellation Leo approximately 16° above the Moon.
